## Abstract

The analogs of the Tröger's base, 7,17-methano-6,7,16,17-tetrahydrodiacridino-[3,4-*b*:3',4'-*f*]-[1,5]-diazocine was prepared starting from 2-aminoacridine instead of 3-aminoacridine. The new compound, 7,17-methano-6,7,16,17-tetrahydro-diacridino-[2,1-*b*:2',1'-*f*]-[1,5]-diazocine, has been fully characterized by <sup>1</sup>H- and <sup>13</sup>C- NMR spectroscopies using mono- and bi-dimensional techniques. Other aminoacridine derivatives failed to afford Tröger's bases.

## Introduction

Some years ago, Lhomme and his coworkers described the synthesis of the Tröger's base analog, 7,17-methano-6,7,16,17-tetrahydrodiacridino-[3,4-*b*:3',4'-*f*]-[1,5]-diazocine, **2**, from 3-aminoacridine **1**<sup>1,2</sup> and reported its NMR properties<sup>3</sup> and X-ray structure (see Scheme 1).<sup>4</sup> Most important is the fact that this compound interacts differently with DNA than do other intercalants.<sup>5</sup> Then, some of the same workers extended the synthesis and biological studies to other, but always 3-amino- substituted, acridines.<sup>6,7</sup>

Owing to our interest in Tröger's bases<sup>8-11</sup> and in aminoacridines,<sup>12-14</sup> we decided to study the reactivity of these last compounds towards formaldehyde in acid media. Only with 2-aminoacridine, **3**, were we successful in obtaining the Tröger's base, **4**.

Scheme 1

## Results and Discussion

### Chemistry

Compound **4** was prepared according to the method of Tatibouët, Demeunynck and Lhomme<sup>15</sup> from 2-aminoacridine, trifluoroacetic acid, and paraformaldehyde under argon for 24 h at room temperature. The compound was obtained only in 45% yield (isomer **2** was obtained in 90 % yield).<sup>1,2</sup>

We carried out similar reactions with the compounds of Scheme 2.

## Scheme 2

In no case were Tröger's bases identified; only intermediate compounds were isolated, in very low yields.

### NMR spectroscopy

We have gathered in Tables 1 and 2 all the information available on compound **4**. The protons of the methylene group at position 6 are named 6n (*endo*) and 6x (*exo*). We are using the numbering of Tröger's base:

The aromatic protons were assigned using double resonance and NOEDIF experiments. The  $^{13}\text{C}$  NMR spectrum was assigned using first a DEPT experiment to identify the quaternary carbon atoms and then 2-dimensional  $^{13}\text{C}$ - $^1\text{H}$  HMQC (one bond)- and HMBC (long distance) correlations.

The assignments in Table 2 are consistent both with other publications dealing with Tröger's bases,<sup>8,10</sup> or with acridines.<sup>12-14</sup>

## Conclusions

The formation of Tröger's bases from aminoacridines and their derivatives (acridin-9-ones, acridin-9-thiones) is a reaction of limited scope. Both **2** and **4** are "bent" isomers, which is the normal result in acridines:<sup>16-20</sup> they cyclize towards the *peri*- position. For the moment, there is no hope of obtaining "linear" compounds such as **2b** and **4b**, that would be very interesting scaffold structures.

## Experimental Section

**General Procedures.** Melting points were determined with a hot-stage microscope and are uncorrected. Column chromatography was performed on silica gel (Merck 60, 70–230 mesh). NMR spectra were recorded on a Bruker AC 200 (200.13 MHz for  ${}^1\text{H}$ , and 50.32 MHz for  ${}^{13}\text{C}$ ) and Bruker Avance-300 (300.13 MHz for  ${}^1\text{H}$  and 75.48 MHz for  ${}^{13}\text{C}$ ) spectrometers using standard conditions. Chemical shifts ( $\delta$ , in ppm) are referred to internal  $\text{Me}_4\text{Si}$ . Mass spectra (HRMS) at 70 eV, using the electron-impact mode, were obtained on a VG Autospec spectrometer by “Laboratorio de Espectrometría de Masas-UAM, Madrid”.

## Syntheses
