### Abstract

Ten title compounds were synthesized by N-alkylation of pyrazoles with 2-iodoacetanilides; they were characterized using spectroscopic methods and pharmacologically tested. Acute toxicity, local anesthetic and anti-arrhythmic activities were assessed using established protocols.

**Keywords:** Acetamides, pyrazoles, local anesthetics

---

### Introduction

According to findings by Löfgren, a local acetanilide anesthetic, such as lidocaine, should contain a lipophilic aromatic structure, a tertiary hydrophilic amino group, and between these two moieties an anesthesiophoric group (ester, ether, amino, carbonyl, amide).<sup>1-3</sup> Usually, an amide as the anesthesiophoric group provides higher activity.<sup>1</sup>

In previous papers we reported the synthesis, characterization and pharmacological tests of some *N*-substituted 2-(1*H*-pyrazol-1-yl)acetamides.<sup>4-6</sup> The present paper reports on the synthesis and characterization of *N*-(chlorophenyl)-substituted 2-(1*H*-pyrazol-1-yl)acetamides. This research was devised to investigate the influence of the *N*-(chlorophenyl) substituents on the pharmacological activity of the new compounds was put in evidence.

## Results and Discussion

Treatment of *N*-(chlorophenyl)-2-iodoacetamides **1a,b** with pyrazoles **2** in DMF in the presence of sodium carbonate afforded *N*-(chlorophenyl)-2-(1*H*-pyrazol-1-yl)acetamides **3** (Scheme 1). Commonly, lidocaine and analogues are prepared by the reaction of 2-chloroacetanilides with amines. 2-Chloroacetanilides obtained by methods reported by Löfgren<sup>1</sup> and Büchi<sup>7</sup>, did not react with pyrazoles **2**. Therefore, we employed the more reactive 2-iodoacetanilides **1** obtained from 2-chloroacetanilides with sodium iodide in acetone under reflux.<sup>8</sup>

**Scheme 1**

The proposed structures are in good agreement with spectral data. A characteristic feature of the <sup>1</sup>H-NMR spectra of **3aa** and **3ba** is the H-4 signal appearing as a doublet of doublets. Also, H-4 in compound **3ae** appears as a quartet as a result of a long range coupling with the 5-methyl group with a coupling constant  $J = 0.8$  Hz. The multiplicity of H-3 in pyrazoles **3aa** and **3ba** results from coupling with H-4 ( $^3J = 1.9$  Hz).

The positions of the methyl and phenyl groups in compound **3ae** were determined on the basis of chemical shifts in the <sup>1</sup>H and <sup>13</sup>C-NMR spectra, by NOE experiments and by comparison with <sup>13</sup>C-NMR data for similar compounds.<sup>9-17</sup> Thus, irradiation of the methylene group resulted in an enhancement by 7% of the 5-methyl signal.

### Pharmacological results

The acute toxicity LD<sub>50</sub> of the compounds ranges within 497-625 mg/kg body weight. Compared with lidocaine all the compounds displayed lower toxicity.

With regard to lidocaine, the compound with the highest anesthetic activity was **3ac** with an activity of 81.3%, whereas the least active compound was **3ad** with 44.2% of the reference substance effect. It was established that compounds having chlorine atoms in the *ortho* and *meta* positions of the benzene ring have generally a higher anesthetic activity than those with methyl groups in the same positions.

The compounds with the highest anti-arrhythmic action compared to lidocaine were **3ac** and **3ad** with the same activity of 61.9% of the reference compound. The anti-arrhythmic activity decreases when a chlorine atom is present in *meta* position of the benzene ring, as compared to a methyl group.<sup>4</sup>

## Conclusions

Ten new *N*-substituted 2-(1*H*-pyrazol-1-yl)acetamides **3** were obtained by *N*-alkylation of pyrazoles **1** with *N*-aryl-2-iodoacetamides **1**. Elemental analyses, MS, IR and NMR data are in agreement with the structures of the products **3**.

The anesthetic and anti-arrhythmic activities of the new *N*-substituted 2-(1*H*-pyrazol-1-yl)acetamides **3** were determined. Their potency was found lower than that of lidocaine and quinidine, but their acute toxicity is significantly lower.

## Experimental Section

**General Procedures.** 2-Iodoacetanilides **1** and pyrazoles **2** were prepared according to the literature.<sup>7,8,18</sup> Melting points were recorded with a Boetius apparatus. UV spectra (400–4000 nm) were obtained with a VSU-2P Zeiss-Jena Spectrophotometer, using MgO as a standard. IR spectra (KBr pellets) were measured on a Biorad FTS-135 Spectrometer. NMR spectra of solutions in CDCl<sub>3</sub>, CDCl<sub>3</sub>/TFA and DMSO-*d*<sub>6</sub> were recorded on a Varian Gemini 300 Spectrometer (<sup>1</sup>H: 300 MHz, <sup>13</sup>C: 75 MHz) with reference to tetramethylsilane (TMS) as internal standard. GC-MS data were recorded on a Varian Saturn 2000 GC/MS/MS (70 eV). Elemental analyses were determined on Costech Instruments EAS32 (Center for Organic Chemistry, Spl. Independentei 202B, Bucharest 060023, Romania). Reaction progress and product purity were checked by TLC (silica gel 60F<sub>254</sub>, petroleum ether/ethyl ether/methylene chloride/ethyl acetate 7.5:1:2:1, UV visualization).

***N*-(Chlorophenyl)-2-(1*H*-pyrazol-1-yl)acetamides (**3**). General procedure.** To a solution of *N*-(2- or 3-chlorophenyl)-2-iodoacetamide **1a,b** (2.01 g, 6.8 mmol) and pyrazole **2** (6.8 mmol) in DMF (3 mL) was added sodium carbonate (0.72 g, 6.8 mmol). The reaction mixture was stirred and heated at 60 °C for 5 h. Then the solution was neutralized with a 10% sodium carbonate solution. The precipitate formed was filtered off and recrystallized from 2-propanol.

(vs, CO), 1520 (vs, CN, NH), 1468 (w), 1407 (w)  $\text{cm}^{-1}$ . MS (EI):  $m/z$  (%) 171 (100,  $\text{M}^+$ ). Anal. calcd. for  $\text{C}_{18}\text{H}_{16}\text{ClN}_3\text{O}$ : C, 66.36; H, 4.95; Cl, 10.88; N, 12.90. Found: C, 66.58; H, 5.21; Cl, 11.20; N, 13.11

### Pharmacology

Acute toxicity ( $\text{LD}_{50}$ ), infiltration, local anesthetic action and anti-arrhythmic action were measured using standard techniques.<sup>19-21</sup> The full pharmacological results will be published elsewhere.
