Abstract

A series of mono- or bis-sulfonylthioureas has been synthesized via nucleophilic substitution of potassium sulfonamides and sodium dithiocarbamate in water under mild conditions, and their properties as anion receptors in the absence and presence of K^+ have been investigated by 1H NMR spectroscopy. It was found that calix[4]crown-5 derivative **10** shows much higher selective complexation capability with $H_2PO_4^-$ in the presence of K^+ than in the absence of K^+ , which indicates the physical dimension of K^+ and $H_2PO_4^-$, respectively, matched the corresponding cavity of the host compound.

Keywords: Synthesis, sulfonylthiourea, sulfonamide, dithiocarbamate, anion receptor, water

Introduction

Thioureas are useful reagents for f. ex. anion complexation¹ and sensing², asymmetric catalysts³ and solar cell construction⁴. The derived sulfonylthioureas display a broad spectrum of biological and pharmacological properties with action as antidiabetics⁵, enhancers of parasympathetic system function⁶, anticonvulsants⁷, antiarrhythmics⁸ or herbicides⁹. Furthermore, they are often used as synthetic intermediates¹⁰ for a variety of guanidine drugs and also as building blocks¹¹ in the synthesis of heterocycles. Direct condensation of sulfonylisothiocyanate with amine in dry $CHCl_3$ or CH_2Cl_2 is the general procedure for the synthesis of sulfonylthioureas.¹² Another synthetic route¹³ is nucleophilic addition of sulfonamide and isothiocyanate in the presence of inorganic bases in anhydrous acetone, DMF or DMSO. The two methods are frequently limited by harsh reaction conditions, lower yields, longer reaction times, and use of toxic solvents. To the best of our knowledge, the voluminous literature about applications of sulfonylthioureas does not mention the use of sulfonylthioureas as anion receptors probably due to their inaccessibility

by traditional synthetic methods. We now report the aqueous-phase synthesis of sulfonylthioureas and a study of their properties as anion receptors.

Results and Discussion

Aqueous-phase synthesis of sulfonylthioureas

The aqueous-phase synthetic method we offered holds many advantages such as mild reaction conditions, free organic solvent, high isolated product yields and very short reaction time. Thus it provided a better and more practical alternative to existing procedures. The synthetic route is outlined in Scheme 1. C=S of **12** has been activated by ClCH₂COONa. The reaction time is shorter for the preparation of **7** and **10**. It is because that benzo-18-crown-6 and calix[4]crown-5 can effectively bind K⁺ from **11**. ArSO₂NH⁻ become unsheltered, which makes nucleophilicity of **11** strengthened.

Scheme 1. Aqueous-phase synthesis of derived sulfonylthioures **1-10** under mild conditions.

Sulfonylthioureas **1-10** has been synthesized via nucleophilic substitution of potassium sulfonylthioureas **11** and dithiocarbamate **12** at rt to 50-60 °C within 1.0 h in water. Aqua **11** were prepared from ArSO₂NH₂ and equivalent KOH in water. Corresponding ArSO₂NH₂ for the

synthesis of compound **10** was obtained based on the modified procedures.^{14a,15} Aqua **12** were afforded from sodium dithiocarbamate and ClCH₂COONa in water following the method.^{14b} All new compounds were characterized by IR, ¹H NMR, ¹³C NMR, mass spectra and elemental analysis.

In conclusion, we have designed and developed a convenient, efficient, economically and environmentally benign procedure for the synthesis of sulfonylthioureas which will be studied below for their properties as anion receptors.

Sulfonylthiourea-based properties as anion receptors.

2 and **7–10** were selected as test objects. Their properties as anion receptors were investigated by standard ¹H NMR titration using a ligands concentration (0.1–2.0 mM) and an increasing concentration of appropriate anion to obtain different host : guest ratios (0.1–20 : 1). To ensure the solubility of both organic ligands and inorganic anions, a mixed solvent system (CDCl₃–CD₃CN 4:1, v/v) was used. All anions were added as their tetrabutylammonium salts to minimize possible interactions of sulfonylthioureas with counter cations. The addition of anions led to the down-field shifts of –SO₂NH– signals. Another experiment was carried out repeatedly in the presence of 2 eq. of KBPh₄ by the same procedure as described above.

Results are summarized in Table 1 and 2 where diphenylthiourea is taken as a reference. The binding constants of **8** and **10** towards some anions are too large to be determined accurately by ¹H NMR spectroscopy and the values given are rough estimations.

Table 1. Binding constants of **2**, **7–10**, and Ph-TU^a towards anions^b (¹H NMR titration, 400 MHz, CDCl₃–CD₃CN = 4 : 1, v/v, 25 °C, K_{ass}, M⁻¹)

anion ^b	Ph-TU	Receptor 2	Receptor 7	Receptor 8	Receptor 9	Receptor 10
H ₂ PO ₄ ⁻	420	740	720	51000	1600	350000
HSO ₄ ⁻	170	260	220	1300	350	1470
I ⁻	6	8	11	9	5	165
Br ⁻	10	17	15	14	16	2000
Cl ⁻	13	26	19	18	25	2500

^aPh-TU: diphenylthiourea. ^bCounter-cation: NBu₄⁺.

Table 1 shows that the association constants follow the trend H₂PO₄⁻ > HSO₄⁻ > Cl⁻ > Br⁻ > I⁻ for **2** and **7–10** as well as Ph-TU. The observed binding selectivity can be roughly explained by the anion basicity order. **2** and **7–10** lead to much higher complexation constants if compared with the reference. This can be understood by considering the electron-withdrawing effect of SO₂ groups. The influence of the naphthyl group of **9** is less beneficial for complexation likely because of a decrease in electron delocalization energy. **10** showed higher selective

affinity for H_2PO_4^- due to the enhanced hydrogen bonding ability of the sulfonylthiourea $-\text{NH}$ protons. Most important of all, the cavity of **10** matched the size and shape of given H_2PO_4^- .

Table 2 indicates that **7** and **10** work as a novel bifunctional receptor for simultaneous complexation of K^+ and anions, where the ability of **7** and **10** to bind anions is significantly enhanced when K^+ is bound to the crown moiety. This is supported by their ^1H NMR spectroscopy, in which downfield shifts for sulfonylthiourea protons were observed upon complexation of K^+ at the crown moiety. But, no complexes of crown moiety can be detected when K^+ is replaced by the other metal ion such as Na^+ , Rb^+ , and Cs^+ . By contrast, Ph-TU, **2**, **8**, and **9**, which lack crown ether moiety for K^+ binding, shows a small decrease for anions. **10** can act as a better bifunctional receptor. Selective complexation model of **10** with H_2PO_4^- in the presence of K^+ is depicted in Scheme 2.

Table 2. Binding constants of **2**, **7–10**, and Ph-TU^a towards anions^b (^1H NMR titration, 400 MHz, $\text{CDCl}_3\text{--CD}_3\text{CN}$ 4 : 1, v/v, 25 °C, K_{ass} , M^{-1}) in the presence of (2eq.) K^+ ^c

Anion ^b	Ph-TU	Receptor 2	Receptor 7	Receptor 8	Receptor 9	Receptor 10
H_2PO_4^-	418	735	7500	50000	1590	3700000

^aPh-TU: diphenylthiourea. ^bCounter-cation: NBu_4^+ . ^cCounter-anion: BPh_4^-

Scheme 2. Possible complexation model of **10** with H_2PO_4^- in the presence of K^+

Conclusions

In this study, a series of mono- or bis-sulfonylthioureas as potential hydrogen bond donors to bind some anions, has been synthesized via nucleophilic substitution of potassium sulfonamides and sodium dithiocarbamate in water under mild conditions, and the anion complexation in the absence and presence of K^+ has been examined by ^1H NMR spectroscopy. The presence of electron withdrawing sulfonyl group results in very high binding affinity towards anions compared with reference Ph-TU. **7** and **10** bearing crown ether moiety are found to work as a novel bifunctional receptor for simultaneously selective complexation of K^+ and H_2PO_4^- , where the ability of **7** and **10** to bind H_2PO_4^- is significantly enhanced when K^+ is bound to the crown moiety, whereas receptor **10** shows a much higher complexation degree with H_2PO_4^- due to the cavities of crown moiety and calixarene matching the physical dimensions of K^+ and H_2PO_4^- , respectively.

Experimental Section

General. The reagents used were of reagent grade and used as purchased. Melting points were measured by using a XT-4A Electrothermal micro-melting-point apparatus and are uncorrected. NMR spectra were recorded at 400 (^1H) and 100 (^{13}C) MHz, respectively, on a Bruker Avance III Plus 400 spectrometer in $\text{DMSO}-d_6$ using TMS as internal reference. Infrared spectra were obtained on a Bio-Rad spectrophotometer using KBr pellets. Mass spectra were measured using Agilent 6100B and Agilent 6220 Time-of-Flight LC/MS. Elemental analysis was determined on a Vario EL III elemental analyzer.

Typical procedure to synthesize sulfonylthioureas (1-10). To the aqueous solution of ArSO_2NHK **11** (1 eq.) was dropwise added an aqueous solution of sodium dithiocarbamates **12** (1eq.). After the addition was completed, the reaction mixture was stirred for about 30 min at room temperature and was subsequently heated to 50-60 °C for another 30 min or so. Finally, the mixture was cooled to room temperature. The resulting precipitate was collected by suction filtration and washed successively with H_2O , then dried under vacuum over P_4O_{10} to afford sulfonylthioureas **1-10** in high purity and yields.

Measurement of sulfonylthiourea-based properties as anion receptors

The measurements were performed by ^1H NMR titration experiments in $\text{CDCl}_3\text{-CD}_3\text{CN}$ ($v/v=4 : 1$) at 298 K using a constant host concentration of 2.0 mM and a varying guest concentration of 0.1-20 mM. For each K_{ass} value determination, 5-10 different guest concentrations were taken. As a probe, the chemical shift of the SO_2NH signal was used.

In the presence of K^+ , anion complexation was measured analogously to the above procedure.

The K_{ass} values were calculated by the equation below as described in literature¹⁸.

$$K_{ass} = \alpha / [(1-\alpha) ([G] - \alpha[H])]$$

where $\alpha = (\delta - \delta_0) / (\delta_{\text{max}} - \delta_0)$, δ_0 is the initial chemical shift (host only), δ is the chemical shift at each titration point, and δ_{max} is the chemical shift when the receptor is entirely bound.
