1. Computational details

Quantum-chemical calculations were performed with the Gaussian09 suite¹ employing the CAM-B3LYP density functional in combination with the 6-311G(d,p) basis set. In order to reduce the computational cost, certain molecules were replaced by simplified forms on the basis of a premise that the simplified molecules should have analogous electronic properties as the original ones. Geometry optimizations were performed with tight SCF and convergence criteria and an ultrafine integration grid, applying the GEDIIS optimization algorithm. The nature of each stationary point was confirmed by a frequency analysis. Gibbs free energy is estimated by the sum of the electronic energy and thermal correction to Gibbs free energy (at 298.15 K) attained from frequency calculation. Wiberg bond order was calculated by NBO 5.9 at the same level of theory as geometry optimization. Atomic orbital composition in LUMO was obtained by Hirshfeld method implemented in MULTIWFN 3.3.8.² Time-dependent density functional (TDDFT) calculations were performed at the MPW1PW91/6-311G(d,p) level of theory with solvation in CH₂Cl₂ by applying the polarized continuum model (PCM) including the keyword IOP(9/40=2) in order to output information on smaller contributions to each electronic transition.³
